### DESCRIPTION

The 74HC366 is an advanced high-speed CMOS HEX BUS BUFFER (3-STATE) fabricated with silicon gate C<sup>2</sup>MOS technology.

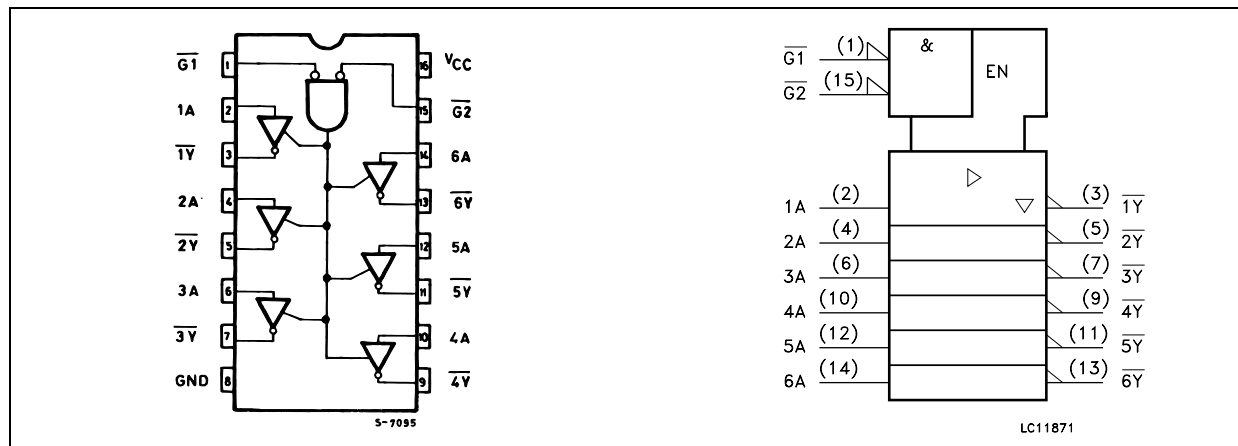

All six buffers are controlled by the combination of two enable inputs ( $\overline{G1}$  and  $\overline{G2}$ ); all outputs of these buffers are enabled only when both  $\overline{G1}$  and

$\overline{G2}$  inputs are held low, under all other conditions these output are disabled in a high-impedance state.

The M74HC366 has inverting outputs.

All inputs are equipped with protection circuits against static discharge and transient excess voltage.

1)  $C_{PD}$  is defined as the value of the IC's internal equivalent capacitance which is calculated from the operating current consumption without load. (Refer to Test Circuit). Average operating current can be obtained by the following equation.  $I_{CC(opr)} = C_{PD} \times V_{CC} \times f_{IN} + I_{CC}/6$  (per gate)
